

# Client-Server Paradigm

- Conceptual basis for many distributed applications
- Based on premise that a program makes a request to which another responds
- Related to remote procedure call mechanism
- Client
  - Any application program
  - Makes a request
  - Awaits a response
- Server
  - Specialized program (process)
  - Awaits a request
  - Computes an answer
  - Issues a response

# Examples Of Standard Servers

- Date and time of day server
- Domain name server
- Electronic mail server
- Remote login server
- File server
- Finger server
- ICMP echo
- UDP echo
- Information server

## Widely Used Application Level Internet Services

- Remote login
- Electronic mail
- File transfer
- World Wide Web

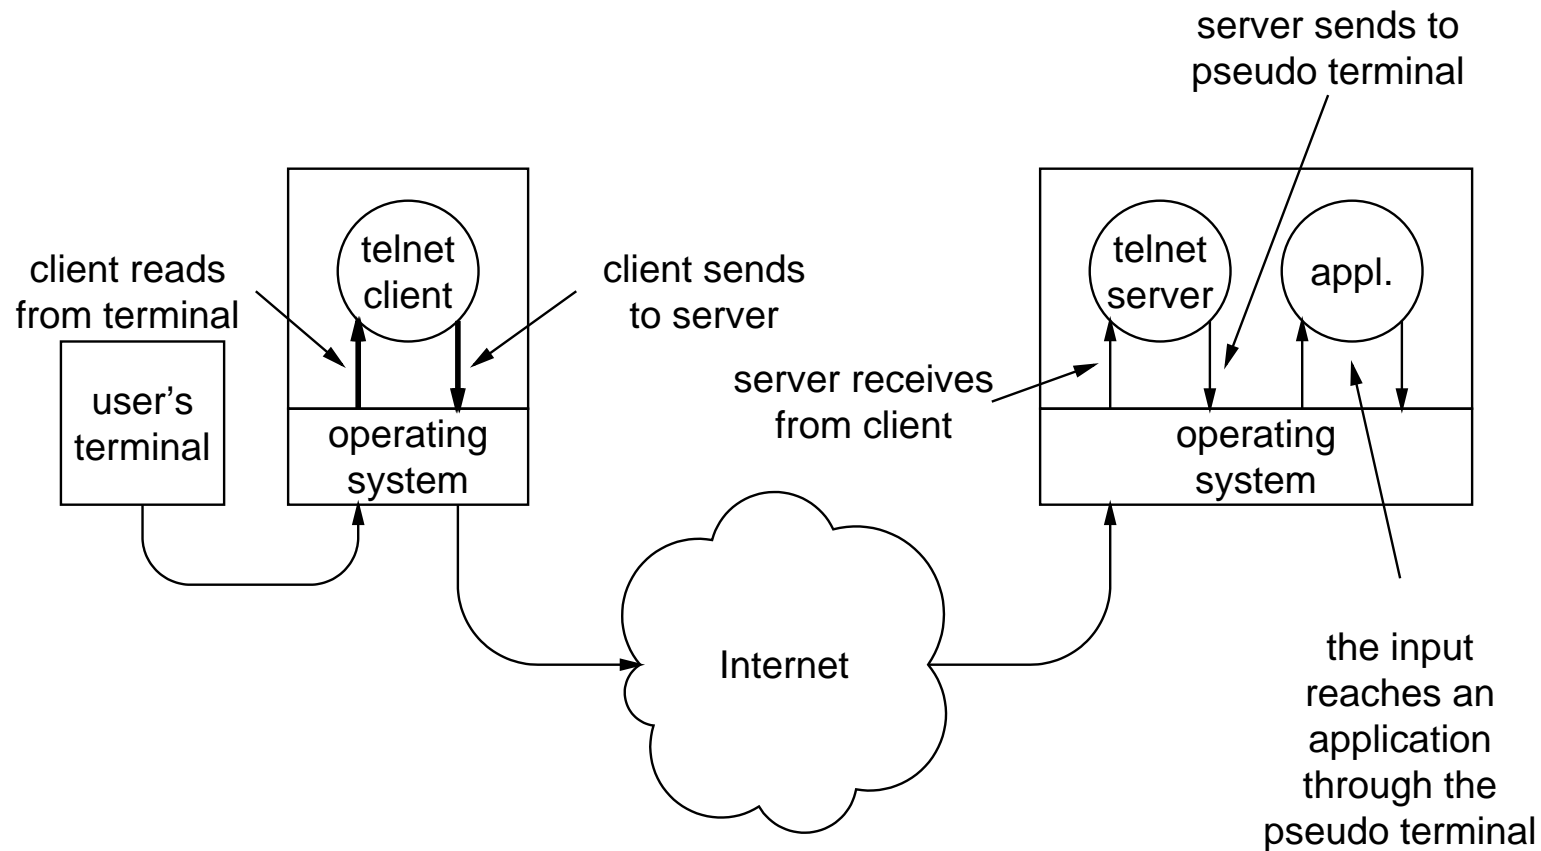

# Remote Login

- Client
  - User invokes client program on local machine
  - Client program
    - Forms connection to server
    - Passes keystrokes to server
    - Displays output from server on terminal
- Server
  - Requires operating system primitive that supplies “pseudo terminal” to running program
  - Master server invoked at system startup
  - Master creates slave to handle each new connection
  - Slave relays characters between TCP connection and pseudo terminal

# TELNET: Internet Standard Remote Terminal Protocol

- Basic facility
- Uses TCP connection to pass data
- Supports options:
  - Character set translation
  - Line terminator
  - Many others

# Illustration of TELNET

- Server process shown is the slave for this connection
- The application is usually a command interpreter

# Rlogin (UNIX Remote Login)

- From 4BSD UNIX
- Passes environment information (e.g., terminal type) to remote machine
- Understands equivalence of login ids
- Preserves UNIX standard input, standard output, standard error
- Nonstandard (limited to UNIX)

# Rsh (UNIX Remote Shell)

- From 4BSD UNIX
- Allows remote command execution
- Honors equivalence of login ids
- Preserves UNIX standard input, standard output, standard error
- Nonstandard (limited to UNIX)

## Example Of Rsh

- Simple Example `rsh ace.cs.ohiou.edu ps`
  - Specifies machine *ace* in domain *cs.ohiou.edu*
  - Executes command *ps*
  - Displays output on user's terminal
- Local redirection
  - Can easily specify remote execution with output to local file

```
rsh ace.cs.ohiou.edu ps > x
```
- Remote redirection
  - Can just as easily specify remote execution with output to remote file

```
rsh ace.cs.ohiou.edu 'ps > x'
```

## SSH - Better Rsh

- Of course, ssh is a much better alternative to rsh
  - Encrypted streams
  - Improved authentication
- Has all the same functionality of rsh

# File Transfer

- Bulk data transfer
- Two standard protocols exist
  - FTP for large transfer
  - TFTP for simpler tasks
- Follows client-server model

# File Transfer Protocol (FTP)

- Defined early in history of Internet
- Heavily used
- Uses TCP for transport
- Provides ability to list directories as well as transfer files
- Client can send or receive files
- Third party transfer supported
- Character translation supported
- Basic file formats defined

# FTP Details

- Client Side
  - Makes a TCP connection to well-known port for control
  - Obtains authorization by sending a login id and password
  - Sends requests to server over control connection
- Server Side
  - Waits at well-known port
  - Uses TELNET for control connection
  - Creates slave to handle each request
  - Makes new TCP connection for each transfer
  - Enforces file access protections

# FTP Example

```
% ftp
ftp> open bigbird.cs.ohiou.edu
Connected to bigbird.cs.ohiou.edu
220 bigbird.cs.ohiou.edu FTP server ready.

Name (bigbird:sdo): anonymous
331 Guest login ok, send ident as password.
Password: sdo@ostermann.cs.ohiou.edu
230 Guest login ok, access restrictions apply.

ftp> ls
200 PORT command successful.
150 Opening data connection for /bin/ls
    (192.5.48.3,1058) (0 bytes).
file1
file2
bigfile
226 Transfer complete. 20 bytes received
    in 0.2 seconds (0.072 Kbytes/s)
```

## FTP Example (continued)

```
ftp> get
(remote-file) file2
(local-file) junk
200 PORT command successful.
150 Opening data connection for file2
    (192.5.48.3,1061) (133120 bytes).
226 Transfer complete. 137888 bytes
    received in 3.7 seconds (36 Kbytes/s)

ftp> close
221 Goodbye.

ftp> quit
```

## FTP Communication Details

### Active Connection

user types	localhost sends	ace sends
ftp ace		
	<i>3-way handshake</i>	
		220 <i>welcome message</i>
username		
	USER anonymous	
		230 Guest login ok, send your complete e-mail address as password.
password		
	PASS sdo@ohiou.edu	
		230 Guest login ok, access restrictions apply.
ls		
	PORT 132,235,3,128,179,186	
		<i>server connects to port 179,186 from port ftp-data</i>
		200 PORT command successful.
	NLST	
		150 Opening ASCII mode data connection for file list.
		<i>file transferred, connection closed</i>
		226 Transfer complete.
quit		
	QUIT	
		221 Goodbye.
	<i>close connection</i>	

# FTP Communication Details

## Passive Connection

user types	localhost sends	ace sends
		<i>... same as active case</i>
ls	PASV	
		227 Entering Passive Mode (132,235,1,2,13,96)
	NLST	
	<i>client connects to port 13.96 on server</i>	
		<i>file transferred, connection closed</i>
		226 Transfer complete.
		<i>... same as active case</i>

# Trivial File Transfer Protocol (TFTP)

- Internet standard
- Alternative to FTP for file transfer only
- Built on UDP
- Uses global file access rights
- Can be implemented in ROM
- Useful for bootstrap
- Useful on small machines

# TFTP Example

- Retrieval of 2454-byte file

# Network File System (NFS)

- Internet file access standard
- Defined by SUN Microsystems, Inc.
- Allows one computer to mount files from another in its directory system
- Application program cannot distinguish local and remote files
- Built on top of SUN's RPC system
- Uses UDP to transfer messages between NFS clients and servers

# Electronic Mail

- Memos delivered from one user to another
- Spooling system accepts outgoing mail and keeps a copy until delivery possible
- Periodic retry (automated)
- Separate standards for mail message format and mail transfer
- High degree of interoperability

# Mail Format (RFC 822)

- Internet standard
- Used by other groups
- Blank line separates header and body
- Specifies headers of the form

`KEYWORD: information`

## Mail Format (continued)

- Only a few keywords are important
  - To:
  - From:
- Other keywords are optional
  - Received-by:
  - Reply-to:
- Others are allowed but not interpreted
  - Environmental-Impact: ...

# Mail Transfer (SMTP)

- Internet standard
- Specifies transfer from machine to machine
- Uses TCP for stream connection

## Electronic Mail Example

- User Smith at machine `ace.cs.ohiou.edu` sends a single mail message to three recipients:
  - `Jones@ohio.edu`
  - `Green@ohio.edu`
  - `Brown@ohio.edu`
- Smith's mail system stores message in spool area and initiates program to transfer message in background
- Background program uses domain name system to map the name *ohio.edu* into an Internet address
- Background program (client) contacts SMTP server at well-known port on machine `ohio.edu` using TCP

## Electronic Mail Example (continued)

```
S: 220 ohio.edu Simple Mail Transfer Service Ready
C: HELO ace.cs.ohiou.edu
S: 250 ohio.edu
C: MAIL FROM:<Smith@ace.cs.ohiou.edu>
S: 250 OK

C: RCPT TO:<Jones@ohio.edu>
S: 250 OK

C: RCPT TO:<Green@ohio.edu>
S: 550 No such user here

C: RCPT TO:<Brown@ohio.edu>
S: 250 OK

C: DATA
S: 354 Start mail input; end with <CR><LF>.<CR><LF>
C: ...sends body of mail message...
C: ...continues for as many lines as message contains
C: <CR><LF>.<CR><LF>
S: 250 OK

C: QUIT
S: 221 ohio.edu Service closing transmission channel
```

## Electronic Mail Example (continued)

- Client and server both close TCP connection
- Server delivers message to Jones' and Brown's mailboxes
- Client (background program) removes the message from the spooling area on ace.cs.ohiou.edu

# X Window System

- Manages multiple, independent windows on a bit-mapped display in a networked environment
- Supports both text and graphics
- Unusual use of client-server paradigm

# X Window System

## (client-server details)

- Server executes on machine with bit-mapped display
  - On workstation under conventional operating system (e.g., UNIX)
  - On special-purpose X terminal with embedded system
- Clients operate on arbitrary hosts
- Special client called *window manager* handles display details, including borders and pop-up menus

# X Window System

(interesting client-server twist)

- Server executes locally (on user's workstation)
- Clients execute remotely
- To create a window containing a login shell for a remote machine, the user must initiate a connection from a client on the remote machine to the server
- User can use *rsh* or *TELNET* to reach remote machine and start a client
- Default remote login client is called *xterm*
