

# Internet Architecture and Philosophy

- Conceptually, TCP/IP provides three sets of services to the user:

- The underlying service provided is “connectionless”.
  - Internet “datagrams” are simply routed independantly between hosts
- The underlying service provided is “unreliable”
  - Any particular datagram might be lost, damaged, delayed, or re-ordered

# Internet Protocol (IP)

- Basic unit of Internet transfer
- Embodies a connectionless packet delivery service
- Analogous to physical network packet
- Composed of
  - Header that contains source and destination
- Internet addresses, datagram type field, etc.
  - Data area that contains data being carried

# IP Datagram Format

- An IP data consists of an IP header of (at least) 20 octets followed by the encapsulated IP data

0	4	8	16	24	31
VERS	LEN	TYPE	SERV	TOTAL LENGTH	
IDENT				FLAGS	FRAGMENT OFFSET
TIME		PROTO		HEADER CHECKSUM	
SOURCE IP ADDRESS					
DESTINATION IP ADDRESS					
OPTIONS					PADDING
DATA					
...					

# Encapsulation

- IP datagram travels in physical network frame
- Complete datagram is treated as data by the hardware
- TCP/IP defines standards for encapsulation on most network hardware technologies

- Complete IP datagram is treated as data in physical network frame
- Encapsulation occurs in network interface software as the last step before the datagram is transmitted

# Datagram Encapsulated In An Ethernet Frame

02	07	01	00	27	ba	08	00	2b	0d	44	a7	08	00	45	00
00	54	82	68	00	00	ff	01	35	21	84	eb	01	01	84	eb
01	02	08	00	73	0b	d4	6d	00	00	04	3b	8c	28	28	20
0d	00	08	09	0a	0b	0c	0d	0e	0f	10	11	12	13	14	15
16	17	18	19	1a	1b	1c	1d	1e	1f	20	21	22	23	24	25
26	27	28	29	2a	2b	2c	2d	2e	2f	30	31	32	33	34	35
36	37														

- IP header follows 14 octet Ethernet frame header and contains 20 octets
- IP source: 132.235.1.1 (84eb0101)
- IP destination: 132.235.1.2 (84eb0102)
- IP type: 01 (ICMP)

# Network MTU

- Each network hardware technology imposes a fixed limit on the maximum size of a packet
- Size limit called *Maximum Transmission Unit* (MTU)
- Encapsulated datagram must be less than network MTU
- Possible solutions
  - Force datagram to be less than smallest possible MTU
    - Inefficient
    - Difficult to know minimum MTU
      - (See RFC 1191 – Path MTU Discovery)
  - Choose initial datagram size that seems appropriate and handle problems later
  - (IP uses the latter)

# Datagram Fragmentation

- Needed when datagram larger than network MTU over which it must travel
- Performed by gateways
- Divides datagram into several, smaller datagrams called fragments
- Each fragment routed as independent datagram
- Final destination reassembles fragments
  - What's the other alternative?
  - Which way is "right" ?

# Datagram Fragmentation Details

- Each fragment is a datagram
- Gateway replicates initial datagram header for all fragments
- Offset field in header gives offset in original datagram for data in this fragment
- Two necessary bits in fragment flags field
  - “More Fragments” bit
    - Can infer “this is a fragment”
    - Can infer “last fragment”
  - Additional bit set in header to indicate “don’t fragment”

# Example Of Fragmentation

Original datagram

Header	data1 400 bytes	data2 400 bytes	data3 400 bytes
--------	--------------------	--------------------	--------------------

Header1	data1
---------	-------

fragment 1 (offset of 0)

Header2	data2
---------	-------

fragment 2 (offset of 400)

Header3	data3
---------	-------

fragment 3 (offset of 800)

- Offset specifies where data belongs in original datagram
- Offset actually stored as multiples of 8 octets
- More fragments bit turned OFF in header of fragment #3

# IP Options

- Option field is broken into 3 sub-fields

0	1	2	3	4	5	6	7
Copy	Class		Option Number				

- Copy
  - 0 means copy only into first fragment
  - 1 means copy into all fragments
- Class
  - 0 – Datagram or network control
  - 2 – Debugging and measurement
  - 1,3 – Reserved

## IP Options (continued)

- A few of the defined IP options:

Option Class	Option Number	Length	Description
0	0	-	End of option list. Used if options do not end at end of header
0	1	-	No operation (used for padding)
0	3	var	Loose source routing. Used to route a datagram along a specified path
0	7	var	Record route. Used to trace a datagram's route
0	9	var	Strict Source Routing. Used to route a datagram along a specified path
2	4	var	Internet timestamp. Record timestamps along route

## Record Route Option

- Original sender enters “record route” option and leaves enough space for the expected number of gateways
- Each gateway along a datagram's path adds its IP address into the header

0	8	16	24
Code (7)	Length (19)	Pointer (11)	
First IP Address			
Second IP Address			
Third IP Address (empty)			
Fourth IP Address (empty)			

- Length - total length of the option, including entries not filled (plus first 3 octets)
- Pointer - offset within the option of the next available slot

# Source Route Options

- IP provides two forms of restricted routing, *strict* and *loose* source routing
  - With *strict* routing, each gateway must be directly connected to the next gateway on the list

0	8	16	24
Code (9)	Length (19)	Pointer (11)	
First Hop IP Address			
Second Hop IP Address			
Third Hop IP Address			
Fourth Hop IP Address			

- Length - total length of the option (plus first 3 octets)
- Pointer - offset within the option of the next address to use
